MAGNITUDE AND INTENSITY (10)

I Main Topics
A Seismic waves
B Magnitude
C Intensity
D Evernden’s equation for intensity decay

II Seismic waves: Nearly-pure elastic waves

A Seismic waves
1 Cause damage
2 Provide quantitative information on source, path(s) of waves
3 Record of waves depends on receiver
II Seismic waves: Nearly-pure elastic waves

B Body waves: travel inside the earth.
   1 P-waves: Primary (compressional) waves. First arrival.
   2 S-waves: Secondary (shear) waves. Second arrival

C Surface waves: travel at the earth's surface
   1 Cause strong ground motion near the epicenter
   2 Polarization
      a Horizontally polarized waves
         i Love waves
         ii especially destructive
      b Vertically polarized waves
         i Rayleigh waves
   5 Amplitudes
      a Tend to saturate (have a ceiling)
      b Scale with shear stress drop ("strength") of fault
II Seismic waves: Nearly-pure elastic waves

C Speed of body waves: $c = L/T$

1. $L =$ wavelength
2. $T =$ period
3. P-wave speed
   $$V_p = \sqrt{\left( K + \frac{4}{3} \mu \right) / \rho}$$
4. S-wave speed
   $$V_s = \sqrt{\mu / \rho}$$

$K =$ bulk modulus
$\mu =$ shear modulus
$\rho =$ density

Key point: $V_p > V_s$
($V_p \approx 1.7 V_s$ for rock)
II Seismic waves: Nearly-pure elastic waves

D Speed of surface waves
   a Horizontally polarized waves
      i Love waves
      ii $V_{Love} = V_s$
   b Vertically polarized waves
      i Rayleigh waves
      ii $V_{Rayleigh} \approx 0.92 V_s$
   c "Feel" deeper as wavelength increases (akin to water waves)
   d Velocity increases with wavelength

III Magnitude

A Magnitude ideally measures only the source strength
B Local (Richter) magnitude ($M_L$)
   1 $M_L = \log (A/A_0)$
   2 $A_0 = \text{amplitude A (in microns) of a Wood-Anderson seismograph}$
      100 km from epicenter
   3 Devised for southern California; reflects wave attenuation there
   4 Does not discriminate between types of waves
   5 Sensitive to surface waves with periods of 0.8 sec
   6 Originally gave $M_L$ to nearest 1/4
   7 Because surface waves saturate, intensity tends to saturate too at $M_L = 6.5$

http://www.eas.slu.edu/eqc/eqc_instruments/wood_and.jpg
III Magnitude

C Surface wave magnitude ($M_s$)
1 Based on surface waves with 20-second periods.
2 Saturates at $M_s = 6.8-7.5$.
3 Has been set to match Richter magnitude for $M_s < 7.5$.

D Body wave magnitude ($M_b$)
1 Based on P-waves with periods of about 1 second
2 Primarily for deep focus events and for small shallow events
3 Saturates at $M_b \approx 6.8$.

E Coda Magnitude: Based on decay of seismic wave amplitude.

F Moment magnitude ($M_w$): based on seismic moment $M_o$
1 $M_w = (2/3) \log M_o - 10.7$ (M_o in dyne-cm)
2 Designed to dovetail with $M_s$ for $M_w < 7.5$

IV Intensity: a measure of the local shaking

A Modified Mercalli Scale (MMI = I to XII)  See next page

<table>
<thead>
<tr>
<th>I. Not felt</th>
<th>II. Weak</th>
<th>III. Weak</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not felt except by a very few under especially favorable conditions</td>
<td>Felt only by a few persons at rest, especially on upper floors of buildings</td>
<td>Felt quite noticeably by persons indoors, especially on upper floors of buildings. Many people do not recognize it as an earthquake. Standing motor cars may rock slightly. Vibrations similar to the passing of a truck. Duration estimated.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>IV. Light</th>

<table>
<thead>
<tr>
<th>V. Moderate tremor</th>
<th>X. Extremely high intensity tremor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Felt generally by everyone. Disturbance of furniture, ringing of some bells.</td>
<td>Great disaster, ruins, disturbance of the strata, fissures in the ground, rock falls from mountains.</td>
</tr>
</tbody>
</table>

IV Intensity: a measure of the local shaking

C Why use intensity?
"All too often, peak acceleration is misguidedly used as a direct measure of earthquake damage potential. It is convenient to discuss an earthquake that has just occurred in terms of its location, magnitude, and peak acceleration. But, as time goes on, magnitude and acceleration may no longer be so relevant. There is a vast gap between peak instrumental acceleration and the base shear coefficients used to design buildings....They can be reconciled only if all the many factors related to the earthquake are considered....it follows that the spikes observed on records have little or no structural design significance....We need to continue to record acceleration and to treat it as a valuable tool but to recognize that it is not a reliable index of damage potential."

J. Blume (1981)

IV Intensity: a measure of the local shaking

C Why use intensity?
"Although intensity is subjective by nature and is by definition linked to the loss extent, it is the only measure available which takes into account such important damage factors as the spectral characteristics and the duration of ground motion in addition to its severity. Therefore, Mercalli intensity is still superior to all known instrumental quantities such as, e.g., instrumental intensity (Housner intensity, Arias intensity) or spectral acceleration, which have failed up to now in reflecting the whole of important damage factors."

(Smolka and Berz, 1981)
Evernden's Rossi-Forel Intensity Formula
(From USGS Prof. Paper 1360)

A Relations attenuation of "radiated seismic energy" (a function of source strength), the distance from the source and the regional attenuation characteristics of the basement rocks (the "path"), and the near surface geology (part of the "path", part of the receiver).

B Uses Rossi-Forel intensity instead of Modified Mercalli because Rossi-Forel intensity apparently scales better with the RMS (root mean square or "average") acceleration over the frequencies of greatest interest. For example, accelerations increase by a factor of 2 for each half unit of increase in the Rossi-Forel scale, but this doesn't hold for the Modified Mercalli scale.

C Focusing (e.g. due to surface topographic effects or the shape of the bedrock surface at the bottom of an alluvial basin) are ignored.

D Empirical

\[ I = 30\log\left(\frac{10^{1.8+1.5M}}{\gamma}\sum_{i=1}^{n} (R_i+C)^{-\gamma}\right) \]

- The term \( n \) is the number of segments the fault will be broken into. For simplicity, we will not subdivide the fault, so \( n = 1 \).

\[ I = 300.5 + \log\left(\frac{10^{1.8+1.5M}}{\gamma}\sum_{i=1}^{n} (R_i+C)^{-\gamma}\right) \]

- The first term in parentheses is the energy (in ergs) as calculated from the magnitude \( M \). This will be a constant and defines the contribution from the source.

- The second term in parentheses is an attenuation term. It decreases with distance from the epicenter and defines part of the contribution from the seismic wave path. This part of the expression simplifies for \( n = 1 \):

\[ I = 300.5 + \log\left(\frac{10^{1.8+1.5M}}{\gamma(R+C)^{-\gamma}}\right) \]
Evernden's Rossi-Forel Intensity Formula

• The log term in equation (3) can be broken down into simpler form:

\[
I = 3 \left[ 0.5 + \log \left( A \left( 10^{11.8 + 1.5M} \right)^{1/\gamma} (R+C)^{-k} \right) \right]
\]

(3)

\[
I = 3 \left[ 0.5 + \log A + \frac{1}{\gamma} \log \left( 10^{11.8 + 1.5M} \right) + \log (R+C)^{-k} \right]
\]

(4)

\[
I = 3 \left[ 0.5 + \log A + \frac{1}{\gamma} \left( 11.8 + 1.5M \right) - k \log (R+C) \right]
\]

(5)

V Evernden's Rossi-Forel Intensity Formula

• Now let's pick a spot on a fault (R=0) in coastal California and assume a magnitude 6.5 earthquake occurs. This is the magnitude that the intensity scale should saturate at, so the expression should yield a Rossi-Forel intensity of X (10). Evernden gives the following parameters: A = 0.779; γ = 4, k = 1.75, C (a pseudo-depth) of 25 km.

\[
I = 3 \left( 0.5 + \log(0.779) + \frac{1}{4} (11.8 + 1.5[6.5]) - 1.75 \log(25) \right)
\]

(6)

Now carry out the arithmetic

\[
I = 3(0.5 + \{-0.108 + 5.388 - 2.446\}) = 10.002
\]

• This is the maximum intensity and can be corrected for the local geology (See p. 161 of PP 1360).
