CAUCHY’S FORMULA AND EIGENVAULES (PRINCIPAL STRESSES) (05)

I  Main Topics

A  Cauchy’s formula

B  Principal stresses (eigenvectors and eigenvalues)

II  Cauchy’s formula

A  Relates traction vector components to stress tensor components (see Figures 5.1, 5.2, 5.3 for derivation)

B  \[ T_i = \sigma_{ij} n_j \] (5.1)

1  Meaning of terms

a  \( T_i = \) traction vector component: \( \vec{T} = T_1 \hat{i} + T_2 \hat{j} + T_3 \hat{k} \)

b  \( \sigma_{ij} = \) stress component

c  \( n = \) unit normal vector. The components \( n_j \) of the unit normal are the direction cosines between \( n \) and the coordinate axes.

2  This represents the physics directly

3  The traction component that acts \( \text{in the } i\)-direction reflects the contribution of the stresses that act \( \text{in that direction.} \)

4  Note that the j’s "cancel out"

5  Note that the subscripts on the T and the n differ

6  \( \sigma \) is symmetric (\( \sigma_{ij} = \sigma_{ji} \)), so ...

C  \[ T_i = \sigma_{ij} n_j \] Standard form of Cauchy’s formula

1  The subscript j’s still "cancel out"

2  The subscripts on the T and the n still differ

3  Easier(?) to remember than “B”
Full expansion

\[ T_i = \sigma_{ji} n_j \]

\[ T_1 = \sigma_{11} n_1 + \sigma_{21} n_2 + \sigma_{31} n_3 \]

\[ T_2 = \sigma_{12} n_1 + \sigma_{22} n_2 + \sigma_{32} n_3 \]

\[ T_3 = \sigma_{13} n_1 + \sigma_{23} n_2 + \sigma_{33} n_3 \]

Matrix form

\[
\begin{bmatrix}
T_1 \\
T_2 \\
T_3
\end{bmatrix} =
\begin{bmatrix}
\sigma_{11} & \sigma_{21} & \sigma_{31} \\
\sigma_{12} & \sigma_{22} & \sigma_{32} \\
\sigma_{13} & \sigma_{23} & \sigma_{33}
\end{bmatrix}
\begin{bmatrix}
n_1 \\
n_2 \\
n_3
\end{bmatrix}
\]

\[
\begin{bmatrix}
T_1 \\
T_2 \\
T_3
\end{bmatrix} =
\begin{bmatrix}
\sigma_{11} & \sigma_{12} & \sigma_{13} \\
\sigma_{21} & \sigma_{22} & \sigma_{23} \\
\sigma_{31} & \sigma_{32} & \sigma_{33}
\end{bmatrix}
\begin{bmatrix}
n_1 \\
n_2 \\
n_3
\end{bmatrix}
\]
\[ \Sigma \mathbf{F}_1 = 0, \text{ so } (\Sigma \mathbf{F}_1)/A = 0. \]

\[ \tau_1(A/A) = (\sigma_{11})(A_1/A) + (\sigma_{21})(A_2/A) + (\sigma_{31})(A_3/A). \]

Similarly, \( \Sigma \mathbf{F}_2 = 0 \) and \( \Sigma \mathbf{F}_3 = 0 \), so

\[ \tau_2(A/A) = (\sigma_{12})(A_1/A) + (\sigma_{22})(A_2/A) + (\sigma_{32})(A_3/A). \]

\[ \tau_3(A/A) = (\sigma_{13})(A_1/A) + (\sigma_{23})(A_2/A) + (\sigma_{33})(A_3/A). \]
Note that $\Delta$ DCB of area A projects onto the $x_1$-$x_2$ plane as $\Delta$ OCB, onto the $x_2$-$x_3$ plane as $\Delta$ OCD, and onto the $x_3$-$x_1$ plane as $\Delta$ OBD. BOP is perpendicular to CD, and because CD is a line in BCD, BOP is perpendicular to BCD. Similarly, COP is perpendicular to BD, so COP is perpendicular to BCD. The intersection of BOP and COP is perpendicular to BCD, and that intersection is OP.

$\omega_1$, $\omega_2$, $\omega_3$, are angles between OP and $x_1$, $x_2$, and $x_3$, respectively.

\[
A_1 = \frac{1}{2} \text{ (base OCD)(height OCD) } = (CD)(OP') = OP'
\]

\[
A = \frac{1}{2} \text{ (base DCB)(height CBD) } = (CD)(BP') = BP'
\]
Derivation of Cauchy’s Equation

Triangles BOP and BP’O are similar right triangles; they both have angle OBP (i.e., $\theta$) in common.

Therefore, angle $BP'O = \omega_1$.

$$\frac{A_1}{A} = \frac{OP'}{BP'} = \cos \omega_1 = n_1$$

Similarly, $$\frac{A_2}{A} = \frac{OP''}{CP''} = \cos \omega_2 = n_2$$ and $$\frac{A_3}{A} = \frac{OP'''}{DP'''} = \cos \omega_3 = n_3$$

$$\tau_1(A/A) = (\sigma_{11})(A_1/A) + (\sigma_{21})(A_2/A) + (\sigma_{31})(A_3/A)$$

becomes

$$\tau_1 = (\sigma_{11})(n_1) + (\sigma_{21})(n_2) + (\sigma_{31})(n_3).$$

Similarly,

$$\tau_2(A/A) = (\sigma_{12})(A_1/A) + (\sigma_{22})(A_2/A) + (\sigma_{32})(A_3/A)$$

becomes

$$\tau_2 = (\sigma_{12})(n_1) + (\sigma_{22})(n_2) + (\sigma_{32})(n_3),$$

and

$$\tau_3(A/A) = (\sigma_{13})(A_1/A) + (\sigma_{23})(A_2/A) + (\sigma_{33})(A_3/A)$$

becomes

$$\tau_3 = (\sigma_{13})(n_1) + (\sigma_{23})(n_2) + (\sigma_{33})(n_3).$$

So $\tau_i = \sigma_{ij} n_j$ but $\sigma_{ij} = \sigma_{ji}$, so $\tau_i = \sigma_{ij} n_j$.
### III. Principal stresses from tensor and matrix perspectives

Consider a plane with a normal vector $\mathbf{n}$ defined by direction cosines $n_1$, $n_2$, and $n_3$. The components of traction $\mathbf{T}$ on the plane, by Cauchy's formula, are $T_i = \sigma_{ij} n_j$. They also are simply the components of $\mathbf{T}$: $T_1=Tn_1$, $T_2=Tn_2$, and $T_3=Tn_3$. The components can be equated:

\[
\begin{bmatrix}
\sigma_{11} & \sigma_{12} & \sigma_{13} \\
\sigma_{21} & \sigma_{22} & \sigma_{23} \\
\sigma_{31} & \sigma_{32} & \sigma_{33}
\end{bmatrix}
\begin{bmatrix}
n_1 \\
n_2 \\
n_3
\end{bmatrix}
=
\begin{bmatrix}
n_1 \\
n_2 \\
n_3
\end{bmatrix}.
\]

(5.2)

The right side of (5.2) can be subtracted from the left side to yield:

\[
\begin{bmatrix}
\sigma_{11} - T & \sigma_{12} & \sigma_{13} \\
\sigma_{21} & \sigma_{22} - T & \sigma_{23} \\
\sigma_{31} & \sigma_{32} & \sigma_{33} - T
\end{bmatrix}
\begin{bmatrix}
n_1 \\
n_2 \\
n_3
\end{bmatrix}
= 0.
\]

(5.3)

Equation (5.3) can be rewritten

\[
[\sigma - I T] [n] = 0,
\]

where $I$ is the identity matrix

\[
I = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.
\]

(5.4)

For any square matrix $[A]$, $[A][I] = [A]$.

(5.5)

According to theorems of linear algebra, equation (5.3) can be solved only if the determinant $|\sigma - I T|$ equals zero:

\[
\begin{vmatrix}
\sigma_{11} - T & \sigma_{12} & \sigma_{13} \\
\sigma_{21} & \sigma_{22} - T & \sigma_{23} \\
\sigma_{31} & \sigma_{32} & \sigma_{33} - T
\end{vmatrix}
= 0
\]

(5.6)

In many cases the components of $\sigma$ are known but $\mathbf{T}$ is must be solved for.

Problems of the form of equation (5.4) are common in many branches of mathematics, engineering, and physics, and they have a special name: eigenvalue problems. The values of $\mathbf{T}$ (i.e., $|I T|$, the principal values) that solve the equation are called eigenvalues, and the vectors $\mathbf{n}$ (the principal directions) that give the directions of $\mathbf{T}$ are called eigenvectors. Because these problems are so common, many mathematics packages, including Matlab, have special routines to solve for eigenvalues and eigenvectors.

Solving (5.6) by hand requires finding the roots of a cubic equation (not easy), so we consider the easier 2-D case, which yields a quadratic equation.
$$\begin{vmatrix} \sigma_{11} - T & \sigma_{12} \\ \sigma_{21} & \sigma_{22} - T \end{vmatrix} = 0 \quad \text{Note: } \begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc$$ (5.7)

$$(\sigma_{11} - T)(\sigma_{22} - T) - (\sigma_{12})(\sigma_{21}) = 0$$ (5.8)

$$T^2 - T(\sigma_{11} + \sigma_{22}) + (\sigma_{11})(\sigma_{22}) - (\sigma_{12})(\sigma_{21}) = 0$$ (5.9)

$$T^2 - T(\sigma_{11} + \sigma_{22}) + [(\sigma_{11})(\sigma_{22}) - (\sigma_{12})^2] = 0 \quad \text{(5.10a)} \quad \text{or} \quad T^2 - T(I_1) + [I_2] = 0 \quad \text{(5.10b)}$$

The term $T$ in equations (5.10) is solved using the quadratic formula:

$$T = \frac{(\sigma_{11} + \sigma_{22}) \pm \sqrt{(\sigma_{11} + \sigma_{22})^2 - 4[(\sigma_{11})(\sigma_{22}) - (\sigma_{12})^2]}}{2} = l_1 \pm \sqrt{l_1^2 - 4l_2}$$ (5.11)

$$T = \frac{(\sigma_{11} + \sigma_{22}) \pm \sqrt{\sigma_{11}^2 + 2\sigma_{11}\sigma_{22} + \sigma_{22}^2 - 4[(\sigma_{11})(\sigma_{22}) - (\sigma_{12})^2]}}{2}$$ (5.12)

$$T = \frac{(\sigma_{11} + \sigma_{22}) \pm \sqrt{\sigma_{11}^2 - 2\sigma_{11}\sigma_{22} + \sigma_{22}^2 + 4(\sigma_{12})^2}}{2}$$ (5.13)

$$T = \frac{(\sigma_{11} + \sigma_{22}) \pm \sqrt{(\sigma_{11} - \sigma_{22})^2 + 4(\sigma_{12})^2}}{2} = l_1 \pm \sqrt{l_1^2 - 4l_2}$$ (5.14)
\[ T = \left[ \frac{\sigma_{11} + \sigma_{22}}{2} \right] \pm \sqrt{\left( \frac{\sigma_{11} - \sigma_{22}}{2} \right)^2 + \sigma_{12}^2} = [c] \pm [r] = \left[ \frac{I_1}{2} \right] \pm \sqrt{\left( \frac{I_1}{2} \right)^2 - I_2} = \sigma_1, \sigma_2 \]

(5.15)

An inspection of the diagram below shows that the first term in brackets in equation (5.15) is the mean normal stress (i.e., the center of the Mohr circle) and the second term in brackets is the maximum possible shear stress (i.e., the radius of the Mohr circle). So the principal stresses lie at the end of a horizontal diameter through the Mohr circle. The terms \( c, r, I_1, \) and \( I_2 \) are called invariants and are independent of the frame of reference.
Example

Suppose the stress state at a point is given by

\[ \sigma_{ij} = \begin{bmatrix} 10 & 3 \\ 3 & 2 \end{bmatrix} \]

where dimensions are in MPa.

Solving for the principal values using eq. (14) yields

\[ T = \frac{(10 + 2)}{2} \pm \sqrt{\left(\frac{10 - 2}{2}\right)^2 + 3^2} = 6 \pm \sqrt{25} = 11 \ and \ 1 \]

Now we substitute these back into (5.3)

\[
\begin{bmatrix} 10 & 3 \\ 3 & 2 - 11 \end{bmatrix} \begin{bmatrix} n_1 \\ n_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \Rightarrow \begin{bmatrix} -1 & 3 \\ 3 & -9 \end{bmatrix} \begin{bmatrix} n_1 \\ n_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}
\]

for \( T = \sigma_1 = 11 \) MPa.

\[
\begin{bmatrix} 10 & 3 \\ 3 & 2 - 11 \end{bmatrix} \begin{bmatrix} n_1 \\ n_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \Rightarrow \begin{bmatrix} 9 & 3 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} n_1 \\ n_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}
\]

for \( T = \sigma_2 = 1 \) MPa.

These relations yield

(a) \(-n_1 + 3n_2 = 0 \ (\sigma_1 = 11 \) MPa) \quad (b) \ 3n_1 + n_2 = 0 \ (\sigma_2 = 1 \) MPa).

From (a), for an eigenvalue (principal value) of 11 MPa, \( n_1 = 3n_2 \).
From (b), for an eigenvalue (principal value) of 1 MPa, \( n_2 = -3n_1 \).

For \( \sigma_1 = 11 \) MPa*

\[ \theta_{x_{1,\text{normal}}} = \theta_{x_1,x_1} = \tan^{-1}\left(\frac{x_2}{x_1} \right) = \tan^{-1}\left(\frac{n_2}{n_1} \right) = \tan^{-1}\left(\frac{3n_2}{n_1} \right) = \tan^{-1}\left(\frac{1}{3} \right) = 18.5^\circ \]

For \( \sigma_2 = 1 \) MPa*

\[ \theta_{x_{1,\text{normal}}} = \theta_{x_1,x_2} = \tan^{-1}\left(\frac{x_2}{x_1} \right) = \tan^{-1}\left(\frac{n_2}{n_1} \right) = \tan^{-1}\left(\frac{-3n_1}{n_1} \right) = \tan^{-1}\left(-3 \right) = -71.5^\circ \]

The two eigenvectors are perpendicular, as they are supposed to be.

* In the first expression for \( \theta \), the normal direction is the \( x_1' \) direction, and \( n_1 \) and \( n_2 \) are the direction cosines for a unit vector along \( x_1' \). In the second expression for \( \theta \), the normal direction is the \( x_2' \) direction, and \( n_1 \) and \( n_2 \) are the direction cosines for a unit vector along \( x_2' \).
Matrix treatments of stress transformation

In matrix form, $\sigma'_{ij} = a'_{i'k}a_{j'k}\sigma_{kl}$ becomes (Mal & Singh, 1991, p. 37)

$$\sigma' = [a] [\sigma] [a^T],$$

where

$$a = \begin{bmatrix}
a_{1'1} & a_{1'2} & a_{1'3} \\
a_{2'1} & a_{2'2} & a_{2'3} \\
a_{3'1} & a_{3'2} & a_{3'3}
\end{bmatrix}$$

$$a^T = \begin{bmatrix}
a_{1'1} & a_{2'1} & a_{3'1} \\
a_{1'2} & a_{2'2} & a_{3'2} \\
a_{1'3} & a_{2'3} & a_{3'3}
\end{bmatrix}$$

The proper order of matrix multiplication is essential in order to reproduce the expansions of lecture 17: $[a] [\sigma] [a^T] \neq [a^T] [\sigma] [a]$.

In MATLAB, equation (5.16) would be written:

```matlab
sigmaprime = a * sigma * a'
```

The term a' signifies $[a^T]$. Matlab also has a function “eig” to find eigenvectors (given in terms of the direction cosines) and eigenvalues.

$$[V,D] = \text{eig} (\sigma)$$
Example

```matlab
» sigmaxy = [10 3; 3 2]

sigmaxy =
    10     3
    3     2

» a = [3/sqrt(10) 1/sqrt(10); -1/sqrt(10) 3/sqrt(10)]
a =
   0.9487    0.3162
  -0.3162    0.9487

» sigmaprime = a*sigmaxy*a'
sigmaprime =
    11.0000   -0.0000
   -0.0000     1.0000

» [V,D] = eig(sigmaxy)

V =
   -0.9487    0.3162  \hspace{1cm} \text{Column 1 in } V \text{ relates to column 1 in } D
   -0.3162   -0.9487  \hspace{1cm} \text{Column 2 in } V \text{ relates to column 2 in } D

D =
    11     0
     0     1
```

The direction cosines (eigenvectors) in the first column of \( V \) correspond to the eigenvalue in the first column of \( D \). The direction cosines (eigenvectors) in the second column of \( V \) correspond to the eigenvalue in the second column of \( D \).
