Salt dissolved in ocean water alters the properties of water.

Freezing point of seawater is \(~ -1.8^\circ C\).

Density continually increases to freezing point.
Drives the circulation mode of the oceans
- completely different from freshwater in lakes

Concentration units for aqueous solutions, gases, and solids

Molar units

1. Molarity = moles per litre of solution = M
   - Commonly used terms include:
     mM = millimolar = millimoles per litre = 10^{-3} moles per litre
     µM = micromolar = micromoles per litre = 10^{-6} moles per litre
     nM = nanomolar = nanomoles per litre = 10^{-9} moles per litre
     pM = picomolar = picomoles per litre = 10^{-12} moles per litre
     fM = femtomolar = femtomoles per litre = 10^{-15} moles per litre
     aM = attomolar = attomoles per litre = 10^{-18} moles per litre
     gM?

2. Molality = moles per kilogram of solvent = m
   - No longer in common use except in some computer programs that calculate distribution of chemical species
3. Moles per kilogram of solution
   - The preferred usage in geochemistry, if not in marine chemistry, about 1.024 smaller than M
   - Sometimes defined as “formality”; however, this latter term has been inconsistently defined in the past and is in disuse

4. Normality = moles of charge equivalents per litre of solution
   (analogous to molarity, except that it refers to charge)
   - Comes from acidity, i.e. moles H⁺ per litre
   - Can also use equivalents per kg of solution (meq/kg)

5. g-atom/litre = mole/litre (a gram-atom is a mole)

6. Mole fraction (used for mixtures of gases and for solid solutions) = \( \frac{n_1}{n_1+n_2+n_3+\ldots} \)

Mass concentration units
1. wt.% = “weight percent” (actually, mass percent)
   - g per 100 g
   - Used for solids

2. ‰ = parts per thousand
   - g/kg for liquids and solids
   - mL/L for gas mixtures

3. Per mil = parts per thousand
   - Term is analogous to “per cent”
   - Is used extensively for isotopic analyses – specifies the deviation from an isotopic standard reference material (SRM)
4. ppm = parts per million
   = µg/g or mg/kg for liquids and solids
   = µL/L for mixtures of gases = ppmv
   • "ppm" is commonly used for solids, whereas "mg/kg" is generally preferred for liquids

5. ppb = parts per billion
   = ng/g or µg/kg

6. mg/L = milligrams per litre
   • commonly used for solutions

---

**Conservative vs. Nonconservative Elements**

- **Conservative**
  - Non-reactive
  - Thus, remain in ocean for long periods (long residence time)
  - Examples: Na, K, S, Cl, Br, Sr, B ("conservative major elements")

- **Nonconservative**
  - Biologically and/or chemically reactive
  - Examples: C, P, Fe
**Chemical composition of seawater**

**Major ions in seawater of salinity 35**

**Constancy of major element ratios**

1776 - Lavoisier - Analyzed English Channel deep seawater
- First seawater analysis

1819 - Marcet - "Specimens of seawater contain the same ingredients all over the world.....these ingredients bear nearly the same proportion to each other.....(the samples) differ only as to the total amount of their saline content."

1884 - Dittmar - Analyzed 77 samples from the HMS Challenger (1872-76)
- Confirmed Marcet's finding, except Ca/Cl was lower in surface seawater as compared to deep seawater (i.e., nonconservative)
Salinity

- Salinity is the amount of dissolved solids in seawater
- Used for determining the density of seawater
- Affects the freezing point of seawater
- Affects the temperature of maximum density of seawater
- Changes in salinity drive thermohaline circulation
- Temperature and salinity characteristics fingerprint origin of water masses
- Accuracy of determination needed is a function of the problem being addressed, e.g. estuaries vs deep ocean

Salinity Measurement – The Past

- Salinity is roughly the number of grams of dissolved matter per kilogram of seawater
- Salinity is difficult to measure gravimetrically because many of the salts are hydrophilic, and some decompose on heating to dryness
- From about 1900 to the 1960’s, salinity was calculated from chlorinity Cl, as determined by titration with silver ion
  \[
  \text{Salinity} = 1.80655 \text{ Cl}
  \]
- As of 1978, it became standard to calculate “practical salinity” S from measured conductivity (PSS-78)
- Note: practical salinity is unit-less, and is not a SI quantity!

Standard Mean Ocean Water (SMOW): \( S = 35, \quad Cl \approx 19\% \)
Salinity Measurement – The Future?

• A salinity measure (g-salt/kg) is needed that is more accurate than conductivity-based Practical Salinity

• Spatial variations in the composition of seawater upset the relationship between
  • Practical Salinity $S_P$ (which is a function of conductivity, temperature and pressure) and
  • Absolute Salinity $S_A$ (defined as the mass of dissolved material per mass of seawater solution)

Salinity Measurement

Improved seawater thermodynamics – How should the proposed change in salinity be implemented?

by SCOR/IASPO Working Group 127
February 2008

Background

The SCOR/IASPO Working Group 127 on the “Equations of State and Thermodynamics of Seawater” is charged with providing improved algorithms and descriptions of the thermodynamic properties of seawater. The working group has made significant progress on many of its goals, and it is now time to seek the advice of the oceanographic community regarding the best practical ways of adopting these developments into oceanographic practice. The Working Group has met twice (once in Wiesbaden in 2005, then in Rejas del Puerto in 2006). Its next meeting is in Berlin in September 2006.

The working group will soon provide the most accurate algorithms to date for the thermodynamic properties of seawater (such as density, entropy, specific heat, expansion coefficient, etc.) based on a new thermodynamic model that more accurately represents absolute salinity. These flow the conductivity-based Practical Salinity. Spatial variations in the composition of seawater upset the relationship between Practical Salinity $S_P$ (which is a function of conductivity, temperature and pressure) and Absolute Salinity $S_A$, defined as the mass of dissolved material per mass of seawater solution. If the thermodynamic properties of seawater are to be written in terms of just one type of salinity, then they are often chosen to be fractions of $S_A$. Moreover, Absolute Salinity is a conservative property that is not conserved when making mixing events whereas Practical Salinity is not conservative.

Absolute salinity for seawater of Reference Composition

In order to progress toward evaluating Absolute Salinity, an initial task was to define the reference compositions of the standards of Standard Seawater. This work has been, and this work is published by Millero et al. (2006a). This abstract of this paper is as follows.

Functional determination of the physical properties of seawater has previously been made for Atlantic surface waters, referred to as “Standard Seawater.” In this paper, a Reference Composition consisting of the major components of Atlantic surface seawater is determined using earlier analytical measurements. The methodology of use salt introduced here is that based on the most accurate physical determination of the composition, adjusted to achieve charge balance and matching two of the 2005 reference seawater Seawater in defined as any seawater that has the Reference Composition and a new Reference Composition Salinity ($S_R$, in defined to provide the best available estimate of the Absolute Salinity of both Reference Seawater and the Standard seawater that was used in the measurements of the physical properties. From a practical point of view, the rule of $S_R$ can be related to the Practical Salinity $S_P$ by

$$S_R = \frac{35.165 04}{35} \times S_P$$

Reference Seawater that has been “standardized” to a Practical Salinity of 35 has a Reference Composition Salinity of exactly $S_R = \frac{35.165 04}{35}$

• Absolute Salinity would:
  • end the ongoing debate in the oceanographic literature about the use of “psu” or “pss”
  • make research papers more readable to the outside scientific community
  • be consistent with SI

A Reference Composition consisting of the major components of Atlantic surface seawater is being determined using existing analytical measurements

A new Reference-Composition Salinity $S_R$ is defined to provide the best available estimate of the Absolute Salinity

The value of $S_R$ can be related to Practical Salinity $S_P$ by

$$S_R = (35.165 04 / 35) \times S_P$$

An algorithm will account for the variation of seawater composition from the standard composition — using either measured parameters (e.g., total alkalinity, silicate and nitrate) or simply the spatial location (longitude, latitude and pressure)
Why are major ion distributions so consistent?

Source of major ions to ocean is **continental weathering**

**Reservoirs and fluxes**

* Excluding oxygen
Residence time of species in seawater affects concentration

Long residence time facilitates good mixing — Marcet’s principle

Variations in salinity depend almost entirely on:

- Balance between evaporation and precipitation
- Extent of mixing between surface and deeper waters
- The salinity of surface sea water:
  - High (up to 37.5) in mid-latitudes due to net evaporation
  - Low at high latitudes (to ~33 above 40°N and S) and at the equator (~35) due to net precipitation
There typically is a halocline from the base of the mixed surface layer to about 1000 m depth

- **At high latitudes:** salinity increases with depth
- **At mid and low latitudes:** salinity decreases with depth
- **Below 1000 m,** salinities are generally between 34 and 35 at all latitudes
Most ocean water falls in a narrow salinity range.

Temperature and salinity are fingerprint characteristics of seawater origin.
The "density anomaly" of seawater in "mass per volume in excess of 1 kg/m$^3$, multiplied by 1000", is designated by the symbol "$\sigma$" (sigma).

In this notation, a specific gravity of 1.025 kg/m$^3$ is expressed as $\sigma = 25$.
